PDF

PDF

analyze this two and provide me top 5 thesis project name for bsc in cse

Looking at both documents, here's the synthesis: the first PDF focuses on your dropout/adaptive-learning topic, and the second broadens it across five topic areas (dropout, purchase intention, product recommendation, customer behavior, demand forecasting) with a project-name vs. thesis-name split. Both consistently push the same principle: a thesis title needs a research angle (explainability, comparison, framework, evaluation) — not just "system I built."

Here's my consolidated top 5, pulling the strongest, most defensible option from each theme:

🏆 1. An Explainable Machine Learning Framework for Customer Purchase Intention Prediction in the Bangladeshi E-Commerce Sector

Ranked #1 in both your source docs indirectly (top pick in doc 2). Strong because "explainable" gives you two research axes: prediction accuracy *and* interpretability (SHAP/LIME), which examiners like.

🏆 2. An Explainable Machine Learning Approach to Early Student Dropout Prediction and Personalized Learning Recommendation in Bangladesh

The top pick from doc 1, and consistently ranked highly in doc 2 as well. Good fit if you already have a dropout/LMS dataset or system in progress — pairs prediction with a recommendation component, giving you two contributions in one thesis.

🏆 3. Comparative Evaluation of Machine Learning Models for E-Commerce Product Demand Forecasting in Bangladesh

Doc 2's #2 pick. Comparative-evaluation theses are easier to scope and defend since the "contribution" is the benchmarking itself — good if you want a more tractable, less ambiguous methodology.

4. Comparative Evaluation of Machine Learning Algorithms for Personalized Product Recommendation in the Bangladeshi E-Commerce Market

Same comparative-study logic as above but applied to recommendation systems — solid if you're more interested in recommender algorithms (collaborative filtering, content-based, hybrid) than classification/prediction.

5. A Machine Learning-Based Framework for Student Performance Prediction and Personalized Learning Recommendation in Bangladeshi Higher Education

A slightly broader alternative to #2 — performance prediction instead of dropout risk, useful if your dataset covers grades/engagement more than attrition specifically.

My honest take: #1 and #2 are the strongest picks overall — both docs independently converge on "Explainable ML" as the differentiator. Between the two, I'd choose based on **what data you can realistically collect**: e-commerce/purchase data (surveys, public datasets like online shoppers intention datasets) is often easier to source than real student dropout records in Bangladesh (privacy/institutional access issues). If data collection is a concern, go with #1; if you already have LMS/student data, go with #2.

Want me to sketch out a rough thesis structure (chapters, methodology outline) for whichever one you lean toward?

provide new and unique suggestion for thesis

Here are fresh directions that go beyond the "prediction + explainability + Bangladesh" template you already have — these lean into more distinctive methodologies or underexplored angles that would stand out more in a thesis defense:

1. A Federated Learning Approach for Privacy-Preserving Student Dropout Prediction Across Bangladeshi Universities

Instead of one institution's dataset, you simulate multiple universities training a shared model without pooling raw student data. Federated learning is still rare in Bangladeshi CSE theses, and it solves a real problem — universities are reluctant to share sensitive student records. Strong novelty angle.

2. A Multimodal Approach to Student Engagement Prediction Using Clickstream, Text, and Attendance Data in Bangladeshi LMS Platforms

Instead of just tabular grades/attendance, you fuse multiple data types (forum posts/text sentiment, click behavior, attendance patterns) into one model. The "multimodal fusion" angle

sentiment, click behavior, attendance patterns, etc) — more technically interesting than a single-source prediction model.

3. Detecting and Mitigating Bias in Machine Learning Models for Student Risk Prediction: A Fairness-Aware Study in the Bangladeshi Education Context

Fairness/bias auditing (across gender, socioeconomic background, geography) is a hot, underexplored research area — very few local theses touch algorithmic fairness. This gives you a genuinely novel contribution rather than "yet another predictor."

4. A Large Language Model-Based Tutoring and Feedback System: Evaluating LLM-Generated Personalized Learning Recommendations Against Traditional ML Approaches

Instead of classic ML (Random Forest/XGBoost) for recommendation, you compare LLM-based (RAG or fine-tuned) recommendation generation against traditional collaborative filtering. Very current, novel, and publishable given how hot LLM-in-education research is right now.

5. A Temporal/Longitudinal Deep Learning Approach to Early Dropout Prediction Using Sequential Academic Records (LSTM/Transformer-Based)

Most dropout-prediction theses use static snapshot data (one row per student). This instead models *sequences* of a student's semester-by-semester performance using LSTM or a small Transformer, predicting risk trajectory over time rather than a single score. More technically rigorous and closer to what top-tier ML conferences publish.

If I had to pick one for genuine novelty-to-feasibility ratio for a BSc thesis: **#3 (fairness-aware) or #5 (temporal/sequential)** stand out most — they're technically achievable with public/synthetic data, and the research angle (bias auditing, or time-series modeling) is something almost no local CSE thesis is doing yet, which makes your defense much stronger.

Want me to pick one of these and sketch a full thesis outline (problem statement, methodology, dataset plan, evaluation metrics)?

for ecommerce

Here are fresh, distinctive e-commerce thesis directions — moving past the "predict X with ML + explainability" pattern into angles that are more novel and defensible:

1. A Federated Learning Framework for Cross-Platform Customer Purchase Prediction Without Sharing Raw Transaction Data

Simulates multiple e-commerce platforms (or vendors within one platform) collaboratively training a purchase-prediction model without pooling sensitive customer data. Solves a real privacy/competitive-data problem — rare in local theses.

2. Detecting Fake Reviews and Rating Manipulation in Bangladeshi E-Commerce Platforms Using Machine Learning and NLP

Instead of predicting purchases, you tackle review fraud — a genuinely underexplored, high-impact problem in the local e-commerce space (Daraz, Evaly-style trust issues). Strong social relevance + real dataset potential (scrape reviews yourself).

3. A Multimodal Deep Learning Approach to Product Recommendation Using Text, Image, and Behavioral Data in Bangladeshi E-Commerce

Fuses product images (CNN), descriptions/reviews (NLP), and clickstream/purchase history into one recommendation model — more technically rich than a single-source collaborative filter.

4. Fairness-Aware Price Prediction and Dynamic Pricing Bias Analysis in Bangladeshi Online Marketplaces

Investigates whether ML-driven dynamic pricing models systematically disadvantage certain seller categories or regions — a fairness/algorithmic-bias angle almost nobody explores locally.

5. A Large Language Model-Based Conversational Recommendation System: Evaluating LLM-Driven Product Discovery Against Traditional Collaborative Filtering in E-Commerce

Builds/evaluates an LLM (RAG-based) shopping assistant vs. classic recommender algorithms — very current given the LLM-in-commerce wave, and gives you a strong comparative-evaluation backbone.

6. Predicting and Explaining Customer Churn in Subscription-Based E-Commerce Using Survival Analysis and Machine Learning

Instead of one-shot "will they buy," this models *when* customers are likely to churn using survival analysis (Cox models, time-to-event) combined with ML — technically more advanced and less common than static churn classifiers.

7. Cross-Border E-Commerce Trust Prediction: Modeling Customer Trust and Purchase Intention for International Sellers on Bangladeshi Platforms

A domain-specific angle: as cross-border e-commerce grows in Bangladesh (AliExpress-style imports), trust modeling combining sentiment, seller reputation, and delivery-reliability data

is a fresh empirical question.

My pick if I had to choose one: #2 (fake review detection) — it's the most practically distinctive, has a real social problem behind it, you can actually scrape your own dataset (reviews from local platforms), and "fraud/manipulation detection" is a much less saturated thesis space than "purchase prediction," which makes your literature review and novelty claim much easier to write.

Want a full outline (problem statement, dataset plan, methodology, evaluation metrics) for one of these?
